# Meridional flows with mass-conservation constraints in the inversions of travel times

$$\delta\tau = -2 \int_{\Gamma_0} \frac{\mathbf{u} \cdot \hat{\mathbf{n}}}{c^2} ds, \quad (1)$$

The solutions here are obtained by fitting stream functions satisfying mass conservation while inverting the travel times.

$$\begin{aligned} \rho u_r &= \frac{1}{r} \frac{\partial \psi}{\partial \theta} + \frac{\cos \theta}{r \sin \theta} \psi, \\ \rho u_\theta &= -\frac{\partial \psi}{\partial r} - \frac{\psi}{r}, \end{aligned}$$

$$\psi'(r, \theta) = \sum_i \sum_j a_{ij} \Phi_i^r(r) \Phi_j^\theta(\theta), \quad \psi' = \psi / \rho$$

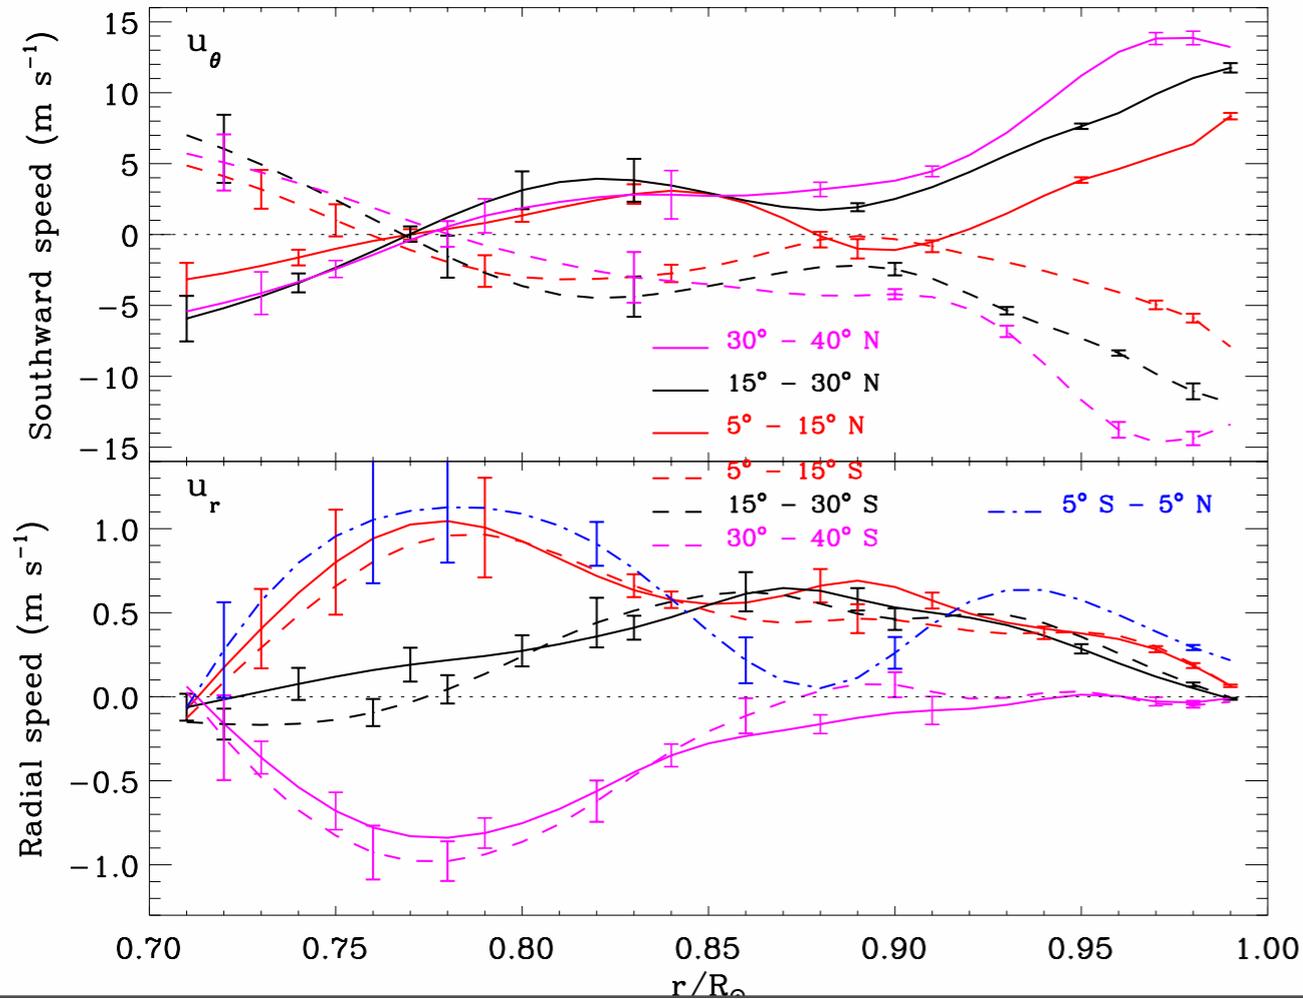

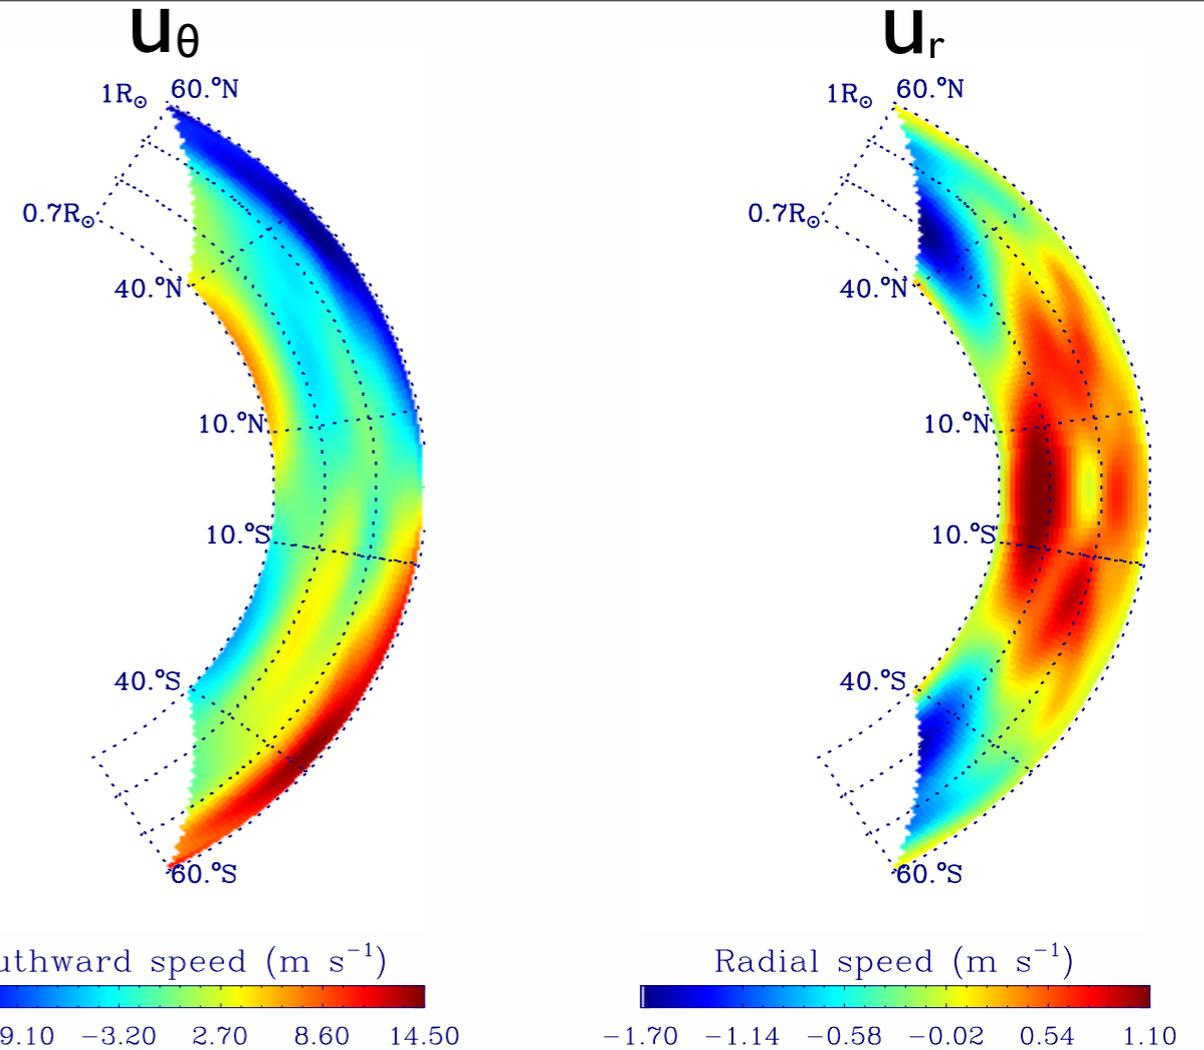

where  $\Phi_i^r(r)$  are the cubic B-spline basis covering  $0.7R_\odot \leq r \leq R_\odot$  and  $\Phi_j^\theta(\theta)$  are the cubic B-spline basis covering  $|\theta - \pi/2| \leq 1.055$ . We use 38 knots in  $r$  which are uniformly spaced in acoustic depth and 31 knots in  $\theta$  which are uniformly spaced in  $\theta$  to define the B-spline

The coefficients  $a_{ij}$  determined using RLS with second derivative smoothing in both  $r$  and  $\theta$  by minimizing

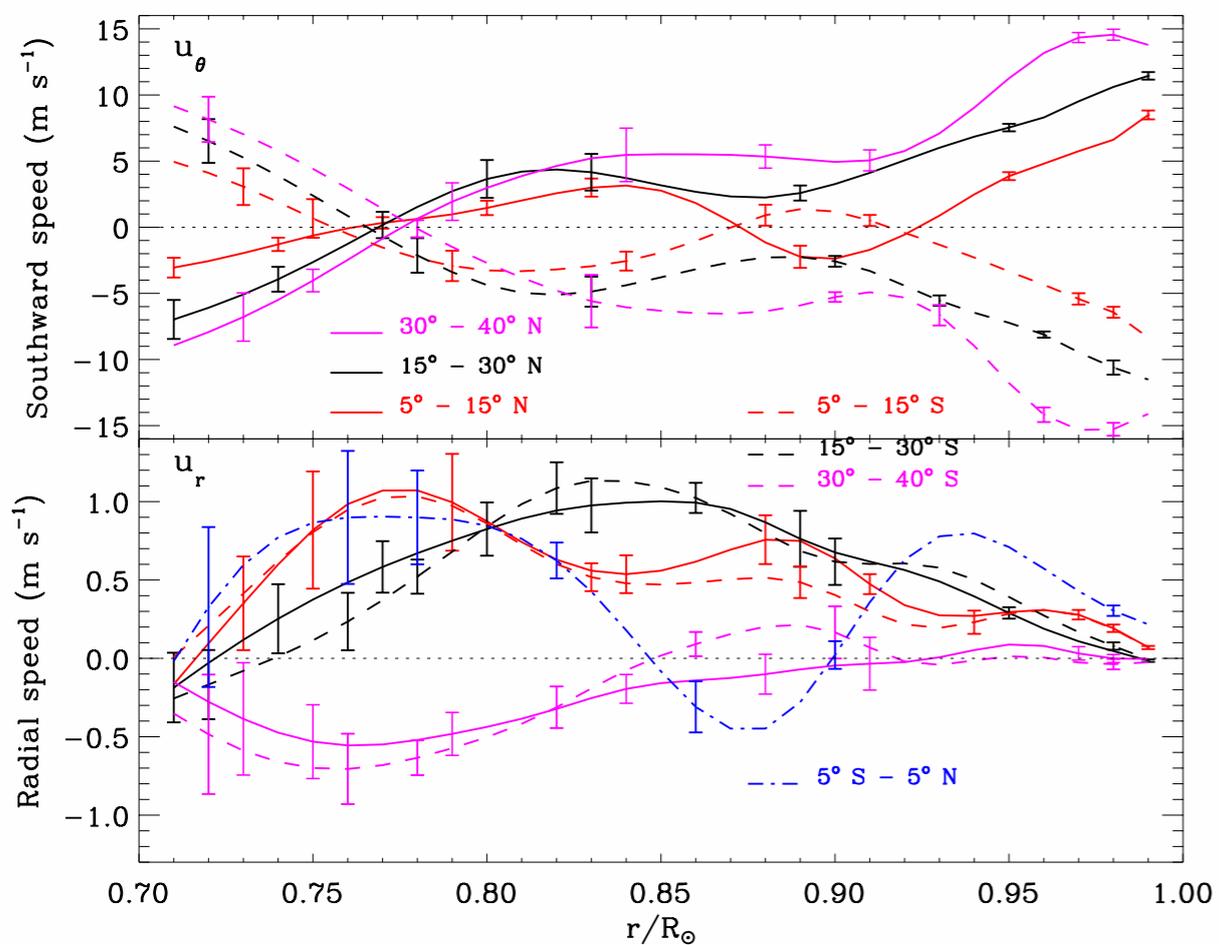

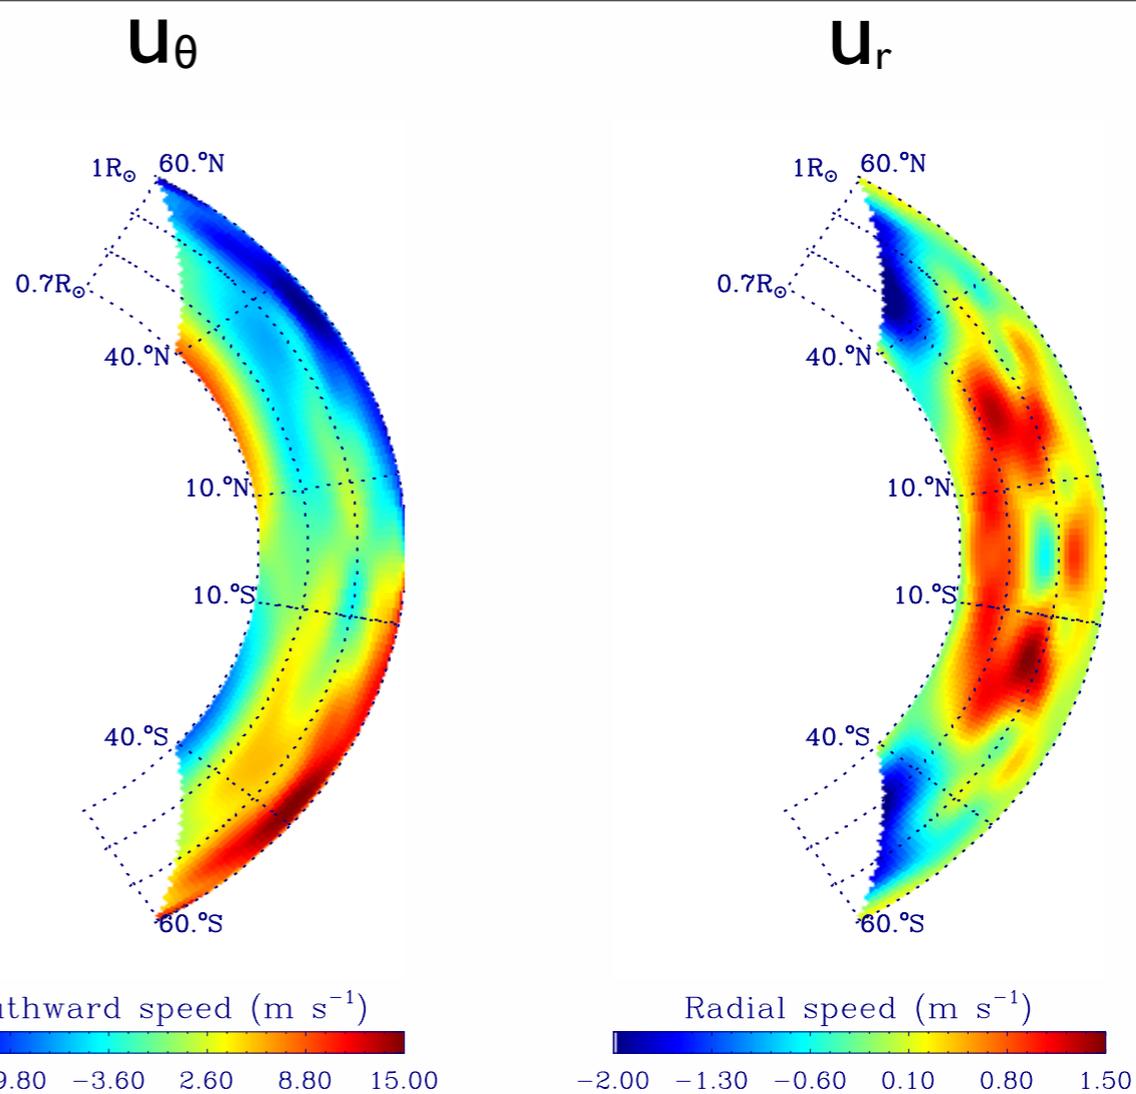

$$\sum_i \left( \frac{d_i}{\sigma_i} \right)^2 + \lambda_r^2 \sum \left( \frac{\partial^2 \psi'}{\partial r^2} \right)^2 + \lambda_\theta^2 \sum \left( \frac{\partial^2 \psi'}{\partial \theta^2} \right)^2$$

$d_i$  are the residuals in the fit to eqn.(1) and  $\sigma_i$  are the corresponding errors in the travel-time differences.  $\lambda_r$  and  $\lambda_\theta$  are the two smoothing parameters.

# A solution with higher smoothing and lower errors.

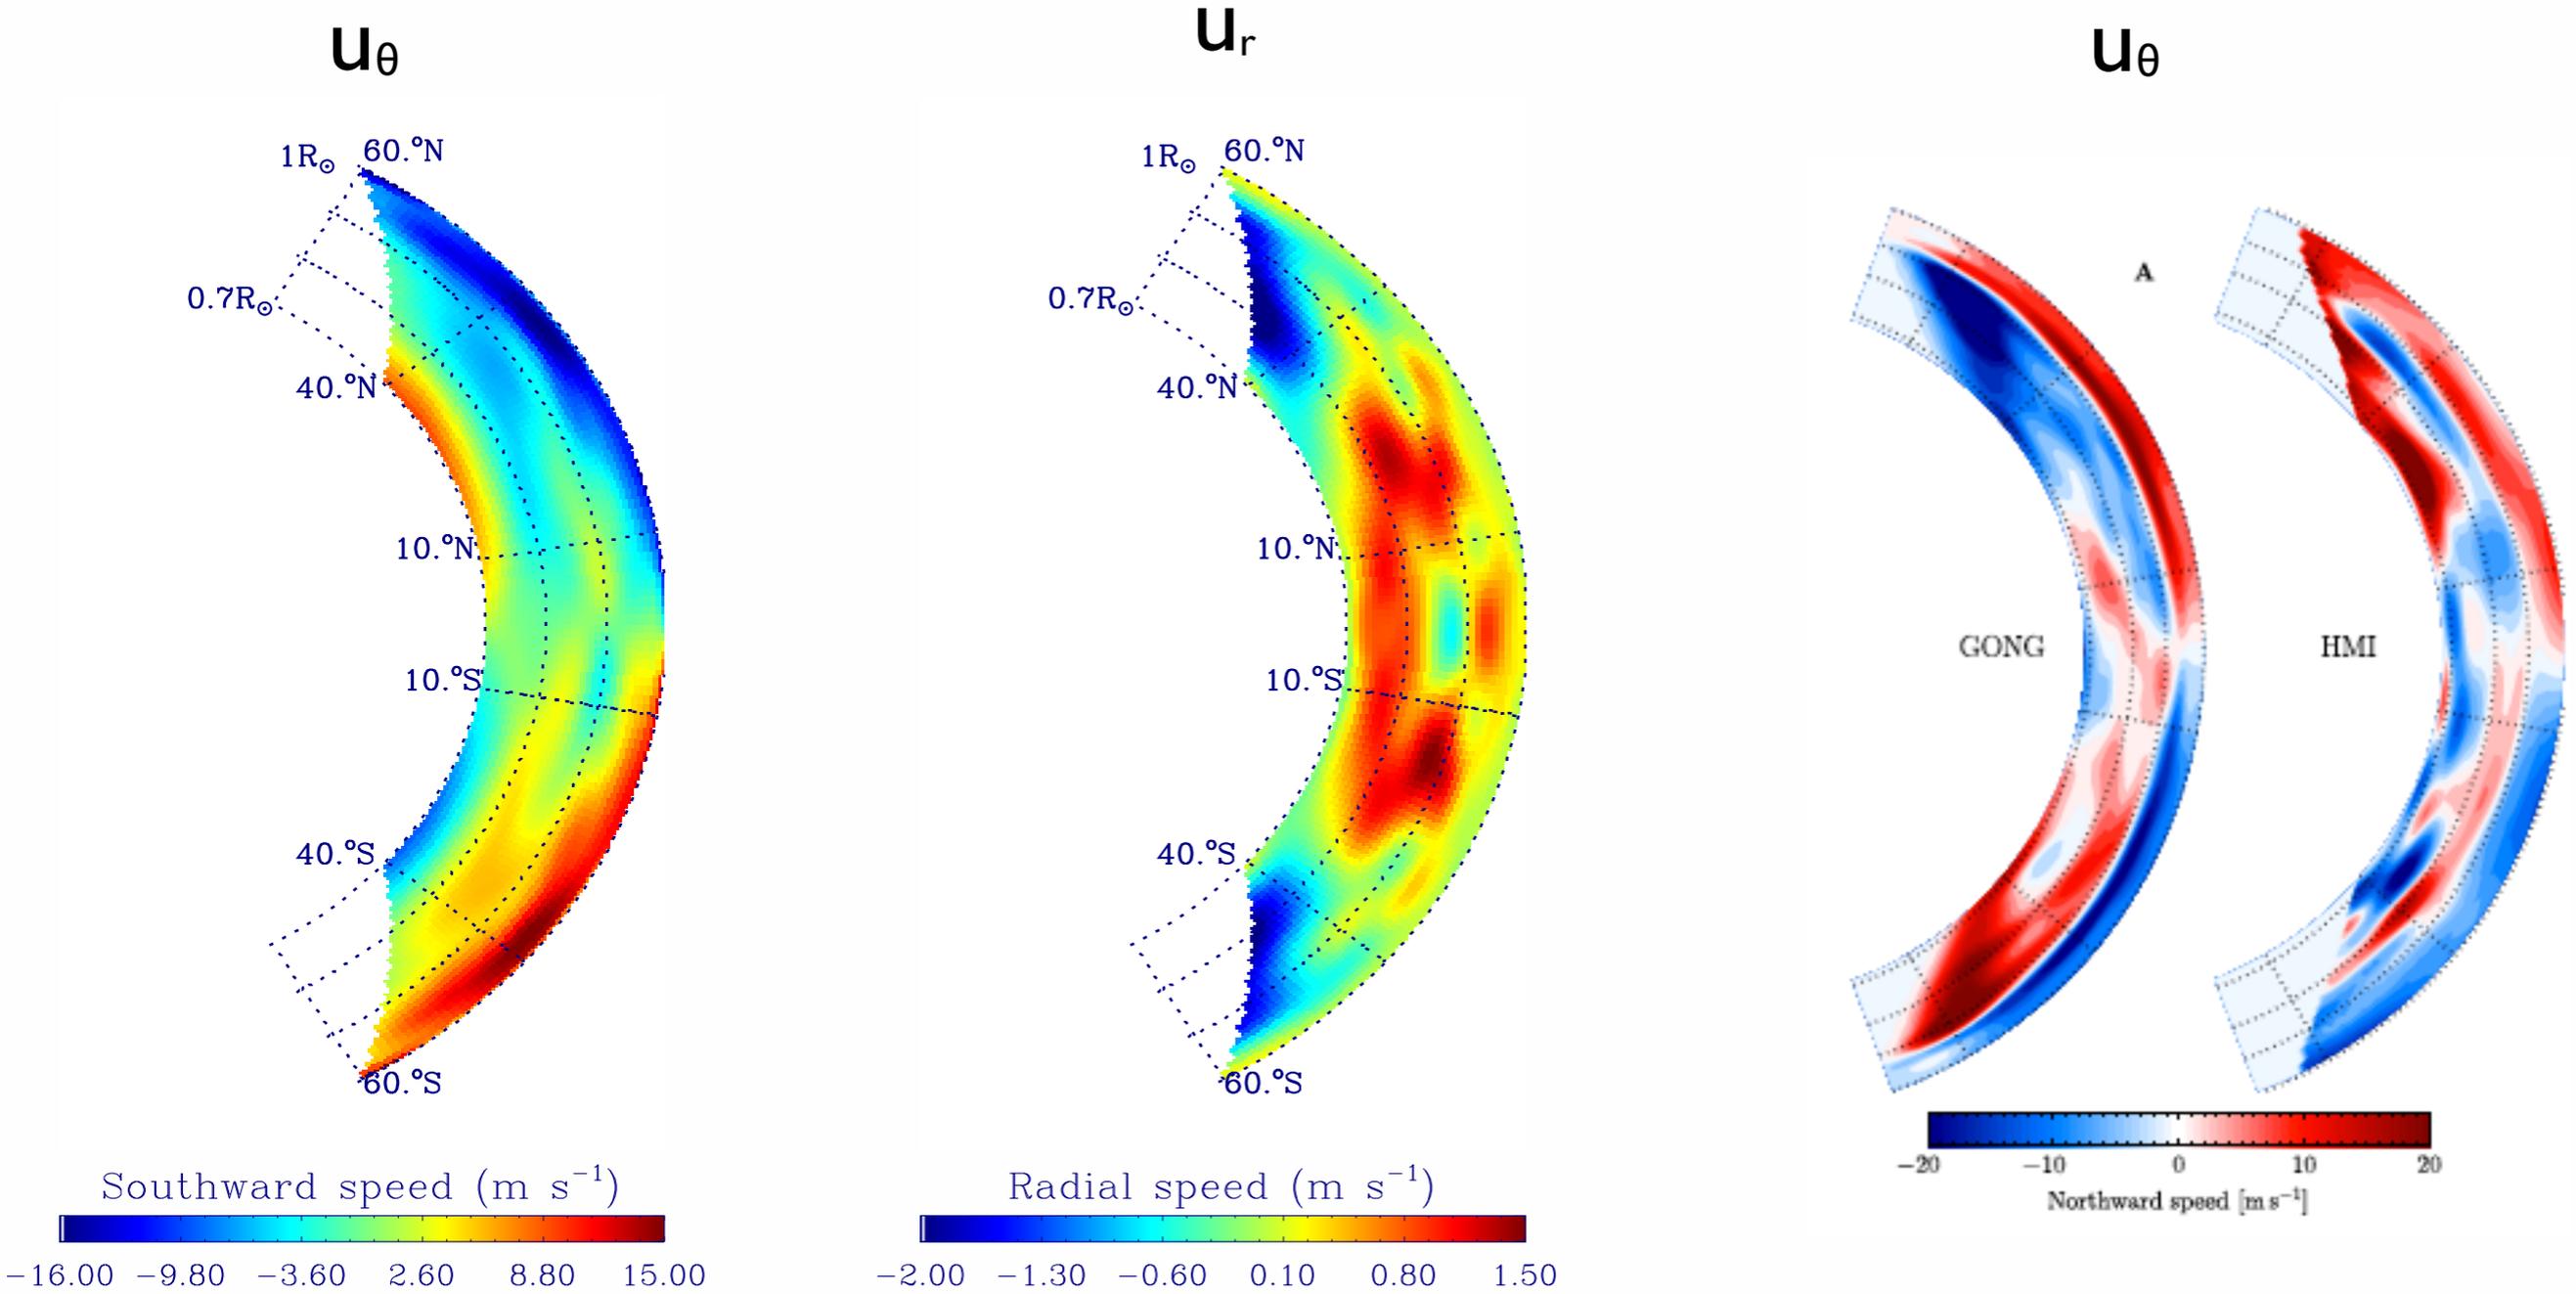

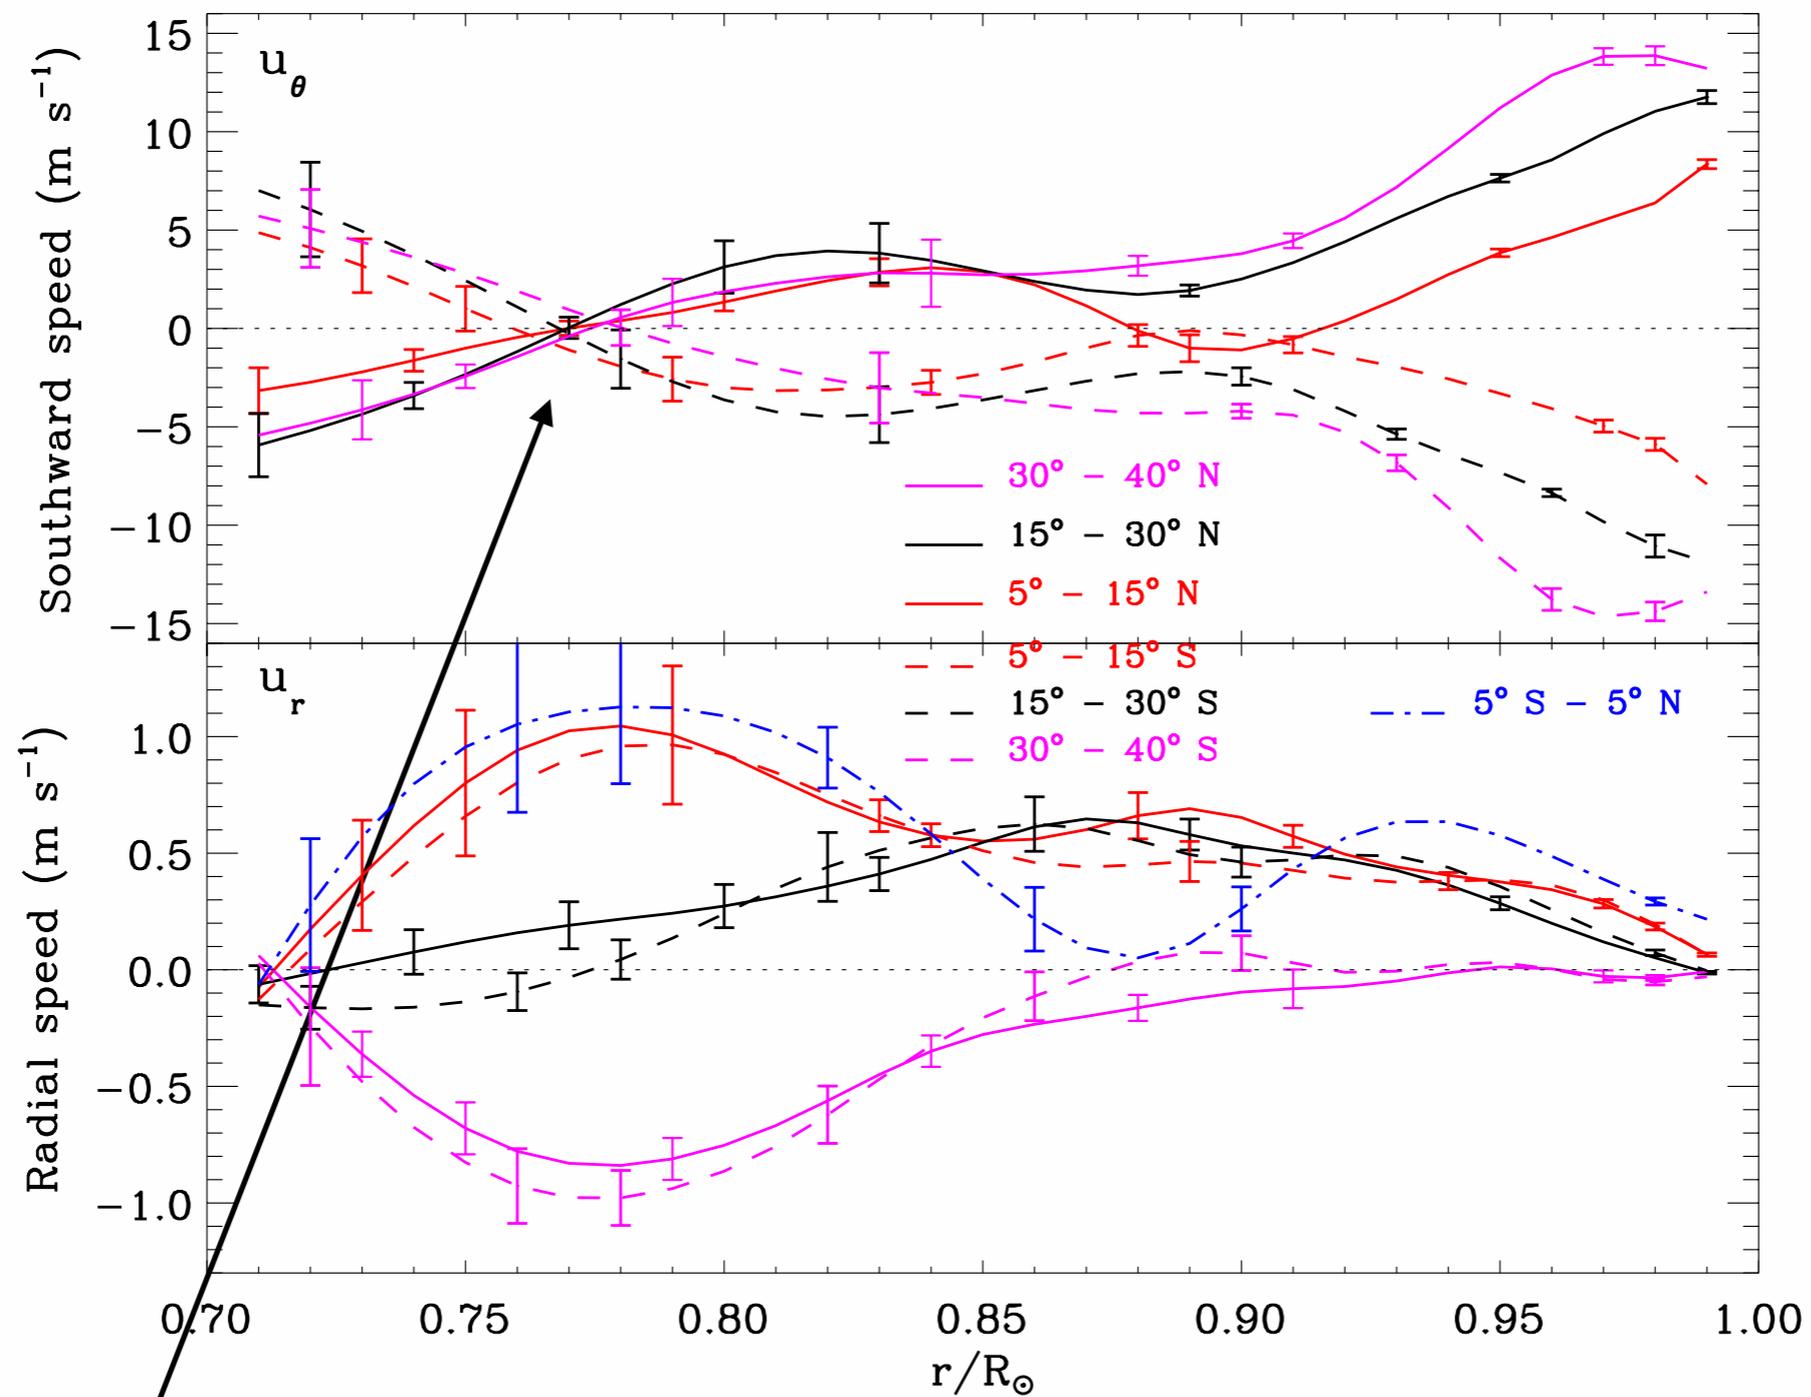

**A solution with lower smoothing and higher errors.**

# Meridional flows with mass-conservation constraints in the inversions of travel times

Rajaguru and Antia (2015)

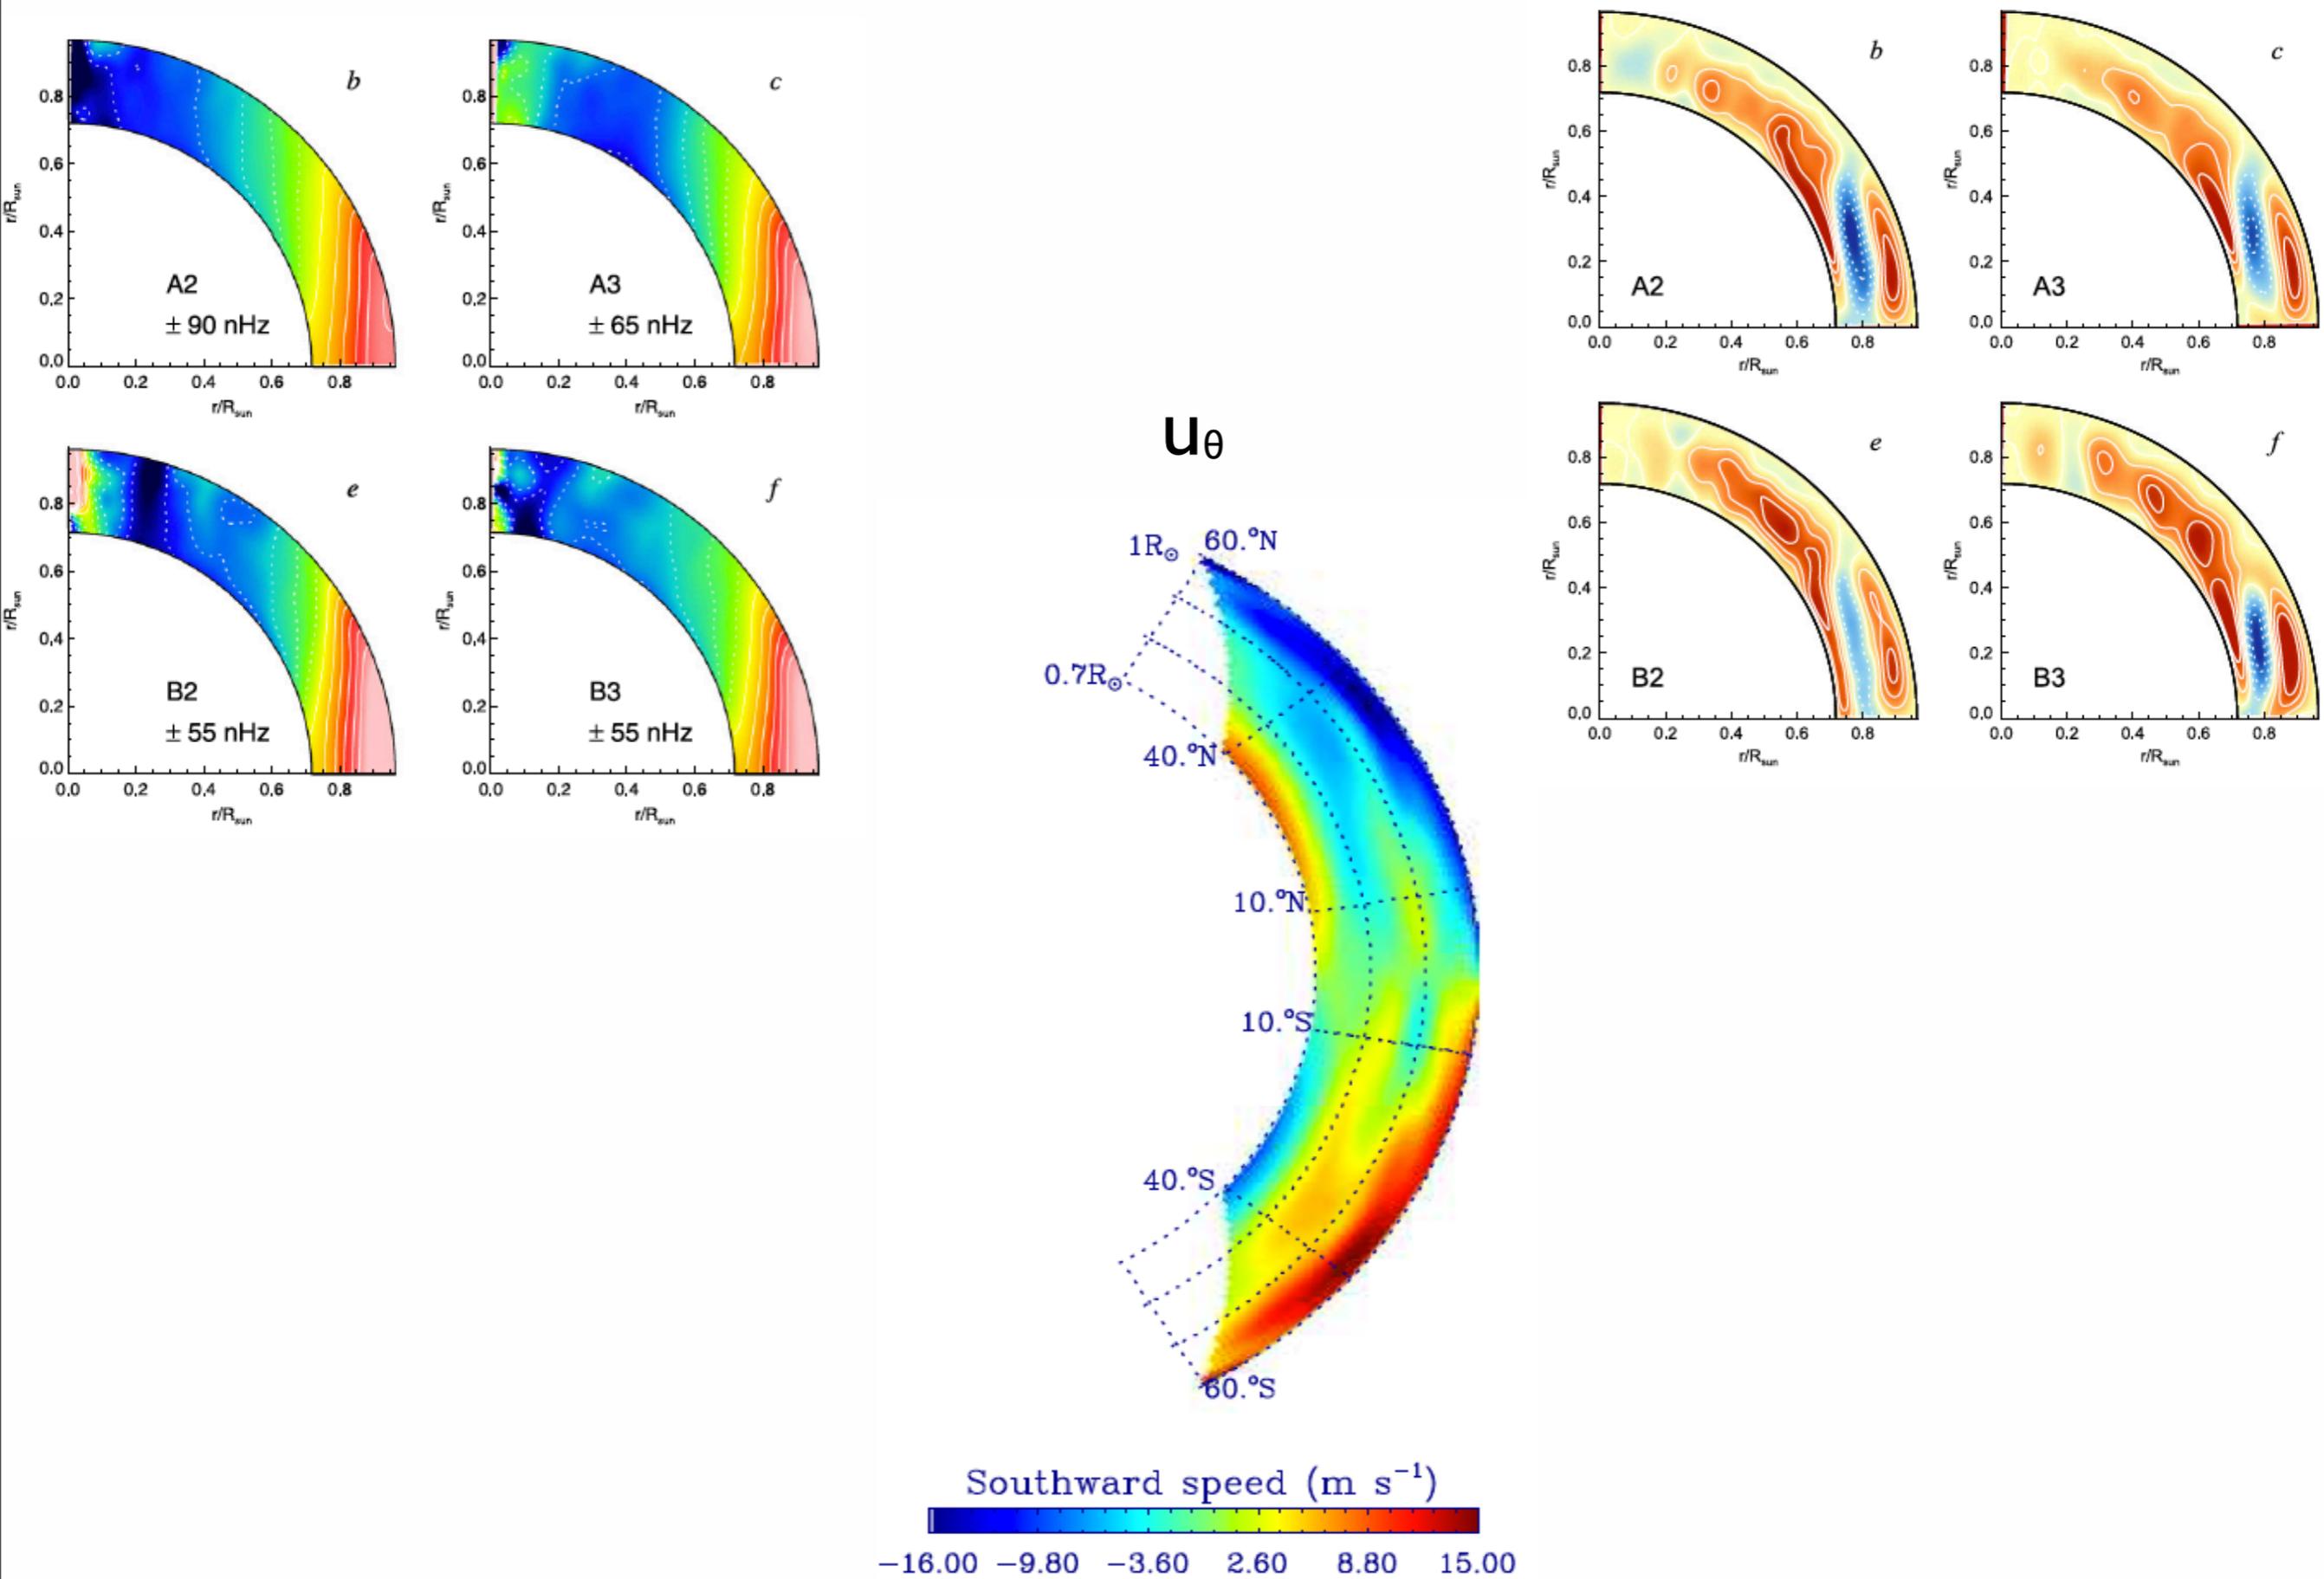

**Likely reversal of flow at about  $0.77 R_{\text{sun}}$ .**

Hints of flow reversals at about  $0.89 R_{\text{sun}}$  are not significant.

A single cell of meridional flow with return flow at about  $0.77 R_{\text{sun}}$  is consistent with the above inversions.

# Numerical models of differential rotation and MC

## Featherstone & Miesch (2015)

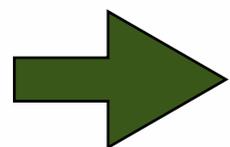

# Main inferences:

- (1) Within errors, the measurements are consistent with a single deep cell of MC
  - return-flow likely below  $0.77 R_{\text{sun}}$
  - broad upwellings near the equatorial regions ( $10^{\circ}\text{S} - 10^{\circ}\text{N}$ ) with radial speeds of  $\sim 1$  m/sec over the depth ranges of  $0.7 - 0.8 R_{\text{sun}}$  and  $0.9 - 0.97 R_{\text{sun}}$
- (2) There are signatures of multi-cellular structure at low latitudes ( $< 25$  deg.) but the signals are close to error limits.

## Reasons for the differences between inferences on the deep structure of MC:

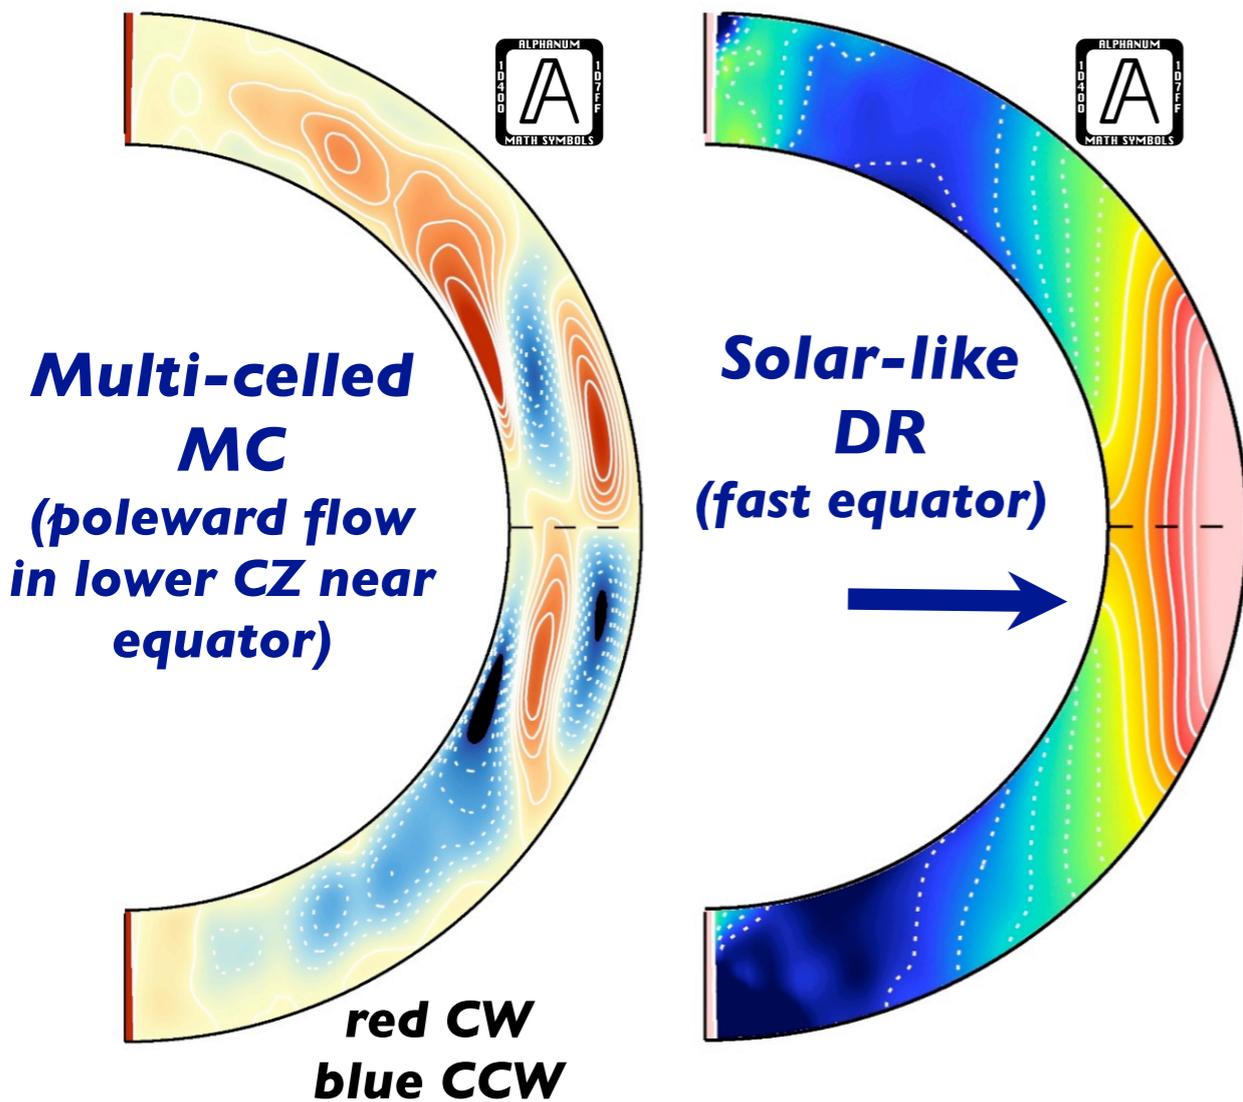

- (1) mass-conservation constraints
- (2) differences in inversion strategy -- sensitivity to errors and systematics in measurements.

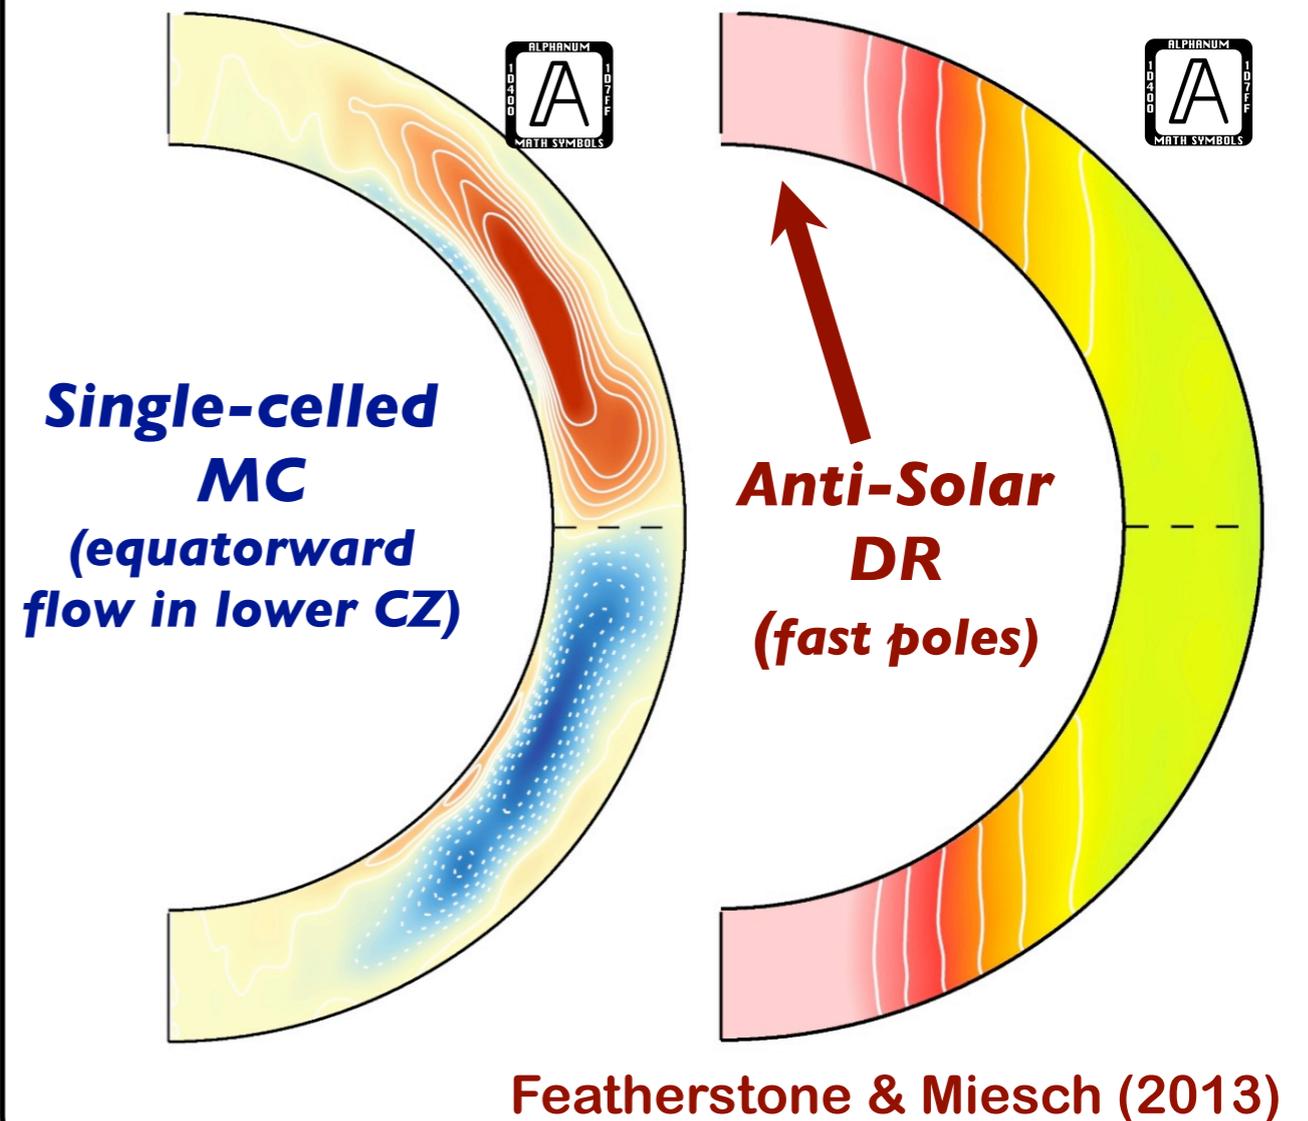

Significant improvements are needed to address the noise and systematics.

# Simulations suggest two different regimes for the Mean Flows

## Fast Rotation ( $Ro \lesssim 0.3$ )

## Slow Rotation ( $Ro \gtrsim 0.9$ )

$$Ro = \frac{U}{2\Omega_0 L}$$
